11 Rehabilitation and Decommissioning

This chapter specifically identifies the following key aspects relating to the rehabilitation of the Project:

- Proposed rehabilitation methods;
- The management of topsoil resources for use in rehabilitation of the site;
- Description of the planned progressive rehabilitation and revegetation of areas across the mine site;
- The integration with ongoing and future rehabilitation activities across the wider mining area; and
- Rehabilitation monitoring and maintenance requirements which may apply.

This chapter sets out acceptable and realistic criteria for rehabilitation and closure that would allow the Project to meet the principles of Ecologically Sustainable Development (ESD) without any unacceptable liability to the State. Without effective rehabilitation, mining has the potential to permanently reduce the capacity of land and ecosystems to provide economic and ecological services and be unsafe for future use.

Matters raised in submission to the Environmental Impact Statement (EIS) relating to Chapter 11 – Rehabilitation and Decommissioning were predominately focused on:

- The number of samples used in the assessment in respect of nominated guidelines;
- The validity of assumptions in respect of regional strata;
- Additional interpretation of the geochemical data; and
- The management of sodic and dispersive soils.

This revised chapter provides additional information in response to the submissions relating to EIS Chapter 11 – Rehabilitation and Decommissioning. Appendix A13 includes the full details of all submissions received for the Project.

11.1 Revised Project Overview

Central Queensland Coal Proprietary Limited (Central Queensland Coal) and Fairway Coal Proprietary Limited (Fairway Coal) (the joint Proponents), propose to develop the Central Queensland Coal Mine Project. As Central Queensland Coal is the senior proponent, Central Queensland Coal is referred to throughout this Supplementary Environmental Impact Statement (SEIS). The Project comprises the Central Queensland Coal Mine where coal mining and processing activities will occur along with a train loadout facility (TLF).

The Project is located 130 km northwest of Rockhampton in the Styx Coal Basin in Central Queensland. The Project is located within the Livingstone Shire Council (LSC) Local Government Area (LGA). The Project is generally located on the “Mamelon” property, described as real property Lot 11 on MC23, Lot 10 on MC493 and Lot 9 on MC496. The TLF is located on the “Strathmuir” property, described as real property Lot 9 on MC230. A small section of the haul road to the TLF is located on the “Brussels” property described as real property Lot 85 on SP164785.
The Project will involve mining a maximum combined tonnage of up to 10 million tonnes per annum (Mtpa) of semi-soft coking coal (SSCC) and high grade thermal coal (HGTC). The Project will be located within Mining Lease (ML) 80187 and ML 700022, which are adjacent to Mineral Development Licence (MDL) 468 and Exploration Permit for Coal (EPC) 1029, both of which are held by the Proponent. It is intended that all aspects of the Project will be authorised by a site specific environmental authority (EA).

Development of the Project is expected to commence in 2018 with initial early construction works and extend operationally for approximately 20 years until the depletion of the current reserve, and rehabilitation and mine closure activities are successfully completed.

The Project consists of two open cut operations that will be mined using a truck and shovel methodology. The run-of-mine (ROM) coal will ramp up to approximately 2 Mtpa during Stage 1 (Year 1-5), where coal will be crushed, screened and washed to SSCC grade with an estimate 80% yield. Stage 2 of the Project (Year 5 - 20) will include further processing of up to an additional 4 Mtpa ROM coal within another coal handling and preparation plant (CHPP) to SSCC and up to 4 Mtpa of HGTC with an estimated 95% yield. At full production two CHPPs, one servicing Open Cut 1 and the other servicing Open Cut 2, will be in operation. Rehabilitation works will occur progressively through mine operation, with final rehabilitation and mine closure activities occurring between Year 18 to Year 20.

A new TLF will be developed to connect into the existing Queensland Rail North Coast Rail Line. This connection will allow the product coal to be transported to the established coal loading infrastructure at the Dalrymple Bay Coal Terminal (DBCT).

Access to the Project will be via the Bruce Highway. The Project will employ a peak workforce of approximately 200 people during construction and between 250 to 500 during operation, with the workforce reducing to approximately 50 during decommissioning. Central Queensland Coal will manage the Project construction and ongoing operations with the assistance of contractors.

This SEIS supports the EIS by responding to the submissions that were made during the public notification period regarding the original EIS and identifies the material changes to the Project.

### 11.2 Relevant Legislation, Policies and Guidelines

#### 11.2.1 Relevant Legislation

##### 11.2.1.1 Mineral and Energy Resources (Financial Provisioning) Bill 2017

Since the release of the EIS the Queensland Government has introduced the Mineral and Energy Resources (Financial Provisioning) Bill 2017.

The Bill:

- Establishes a new financial assurance system for resource activities in Queensland, including a pooled fund for resource entities that meet the criteria; and

- Reforms the mine rehabilitation process, including requirements for upfront commitments to progressive rehabilitation and mine closure through a Progressive Rehabilitation and Closure Plan (PRCP).

The new requirements for financial assurance and rehabilitation for resources activities is expected to commence on 1 July 2018.
The primary change introduced by the Financial Provisioning Bill is that plans of operations for mining projects with site-specific environmental authorities will be replaced with PRCPs, that will:

- Provide the plan for the mining activity;
- Identify the post mining land use; and
- Detail progressive rehabilitation, including milestones and timeframes. Land will be available for rehabilitation generally if it is not being used for mining, does not contain permanent infrastructure and will not be mined within the next 10 years.

A PRCP guideline will be developed, to assist with the preparation of PRCPs. The detail required for the progressive rehabilitation requirements will not be known until the guideline is released. Central Queensland Coal will, once appropriate guidance is developed and disseminated by the Queensland Government, prepare a PRCP.

### 11.2.1.2 Environmental Protection Act 1994

The *Environmental Protection Act 1994* (EP Act) describes the requirements of applications for a site specific environmental authority including how the land which is the subject of the application will be rehabilitated after each relevant activity ceases. This information is used to aid the Department of Environment and Science (DES) in preparing the draft EA for the Central Queensland Coal project. Rehabilitation requirements are implemented through financial assurance requirements, Plan of Operations and a Rehabilitation Management Plan (RMP), until the guidelines for the preparation of a PRCP are introduced.

**Financial Assurance**

Queensland’s DES will, by condition of the EA, require financial assurances to be lodged before carrying out any activities on the mining leases (s292 of EP Act). Financial assurance provides the government with a financial security to cover any costs or expenses incurred to prevent or minimise environmental harm or rehabilitate or restore the environment, should the EA holder fail to meet their environmental obligations in the EA.

For resource activities, financial assurance is calculated based on the year in which rehabilitation costs are likely to be the highest. The DES Guideline Financial Assurance under the EP Act provides guidance on the circumstances when financial assurance is required, the form of financial assurance, calculation method, application requirements and other matters such as lodging, changing, discharging or claiming financial assurance.

**Plan of Operations**

The Plan of Operations will detail how the Project will implement progressive rehabilitation throughout the operations. The Plan of Operations will include the following (S288 of EP Act):

- Description of all resources activities that will take place on the site during the time frame covered by the plan;
- Proposed program of actions to comply with EA conditions;
- Rehabilitation program for land disturbed or land that will be disturbed during the period of the plan;
• Proposed amount of financial assurance based on the guidelines for calculating financial assurance; and

• Compliance statement describing how a proponent has complied with the EA conditions.

As part of the Project’s EA, the Plan of Operations will be submitted to DES at least 20 business days prior to commencing activities (s287 of the EP Act). The Plan will also be reviewed by an independent, suitably qualified auditor. The Plan of Operations must be renewed on a five-year basis but typically it is renewed more frequently. DES may suspend or cancel the EA in the event of inadequacy or non-compliance of operations in meeting the approved Plan of Operations. It is also an offence under s290 to fail to comply with a Plan of Operations.

Rehabilitation Management Plan

A rehabilitation program for land disturbed during activities associated with the Plan of Operations is a requirement of the EA. A RMP will be developed, guided by the DES Guideline – Rehabilitation requirements for mining resource activities.

Final Rehabilitation Report and EA Surrender

Upon completion of the Project, Central Queensland Coal will be required to submit an EA surrender application. As part of the surrender application, Central Queensland Coal will be required to prepare and submit a progressive or final rehabilitation report to DES for assessment. DES must consider the relevant completion criteria (s318ZI or s268) when deciding whether to certify progressive rehabilitation or whether to approve a surrender application. DES must be satisfied with the rehabilitation before it can certify progressive rehabilitation for part of a mining project or accept the surrender of an environmental authority for the whole of a project.

The discharge of financial assurance is sought after activities have ceased and subject to successful rehabilitation at the time of surrendering the EA. However, DES may, after approving the surrender of an EA, require that the financial assurance remains in force until it is satisfied that no claim is likely to be made in the future (s292 of the EP Act).

11.2.2 Policies

The Australian and New Zealand Minerals and Energy Council (ANZMEC) and the Minerals Council of Australia (MCA) jointly published the Strategic Framework for Mine Closure (ANZMEC and MCA 2000). The framework recognised that the mining industry is responsible for rehabilitation of mine disturbance in an environmentally and socially acceptable way.

The National Strategy for Ecologically Sustainable Development (COA 1992) promotes economic growth that safeguards the welfare of future generations, provides equity within and between generations, protects biological diversity and maintains essential ecological processes and life support systems.

These policies underpin the Queensland rehabilitation requirements.

11.2.3 Guidelines

The Commonwealth Government’s Leading Practice Sustainable Development Program (LPSDP) for the mining industry issued a handbook series in 2006 which has been revised in 2016 (Australian Government 2016). These provide leading practice approaches, attitudes and technologies which have been considered in the proposed rehabilitation of this Project.
Guideline EM1122, Rehabilitation Requirements for Mining Resource Activities (EHP 2014) has been developed by DES and has been used to develop acceptable rehabilitation outcomes and strategies for this Project. The guideline also explains how the administering authority will assess whether progressive or final rehabilitation for either new or established mining projects is satisfactory.

11.3 Key Ecosystem Processes and Functions

Under the new LPSDP's Mining Rehabilitation Handbook, the goal of rehabilitation is to reinstate ecosystem functioning and land productivity to re-establish ecosystem structure and function (Australian Government 2016). To acquire a self-sustaining post-mining land use, species compositions like surrounding ecosystems, and an understanding of the processes and influences within those ecosystems, is vital in designing and implementing a RMP. Ecosystems can be examined on a sliding scale from global, regional, local and micro systems and they contain complex interactions of abiotic (geology, soils, water, atmosphere and land form) and biotic components (plants, animals and decomposers) (Chapin, Matson and Vitousek 2011). These interactions determine the ecosystem structure, function and biodiversity and their understanding is fundamental to mine site rehabilitation.

11.3.1 Climate

The climate of a region, particularly rainfall and temperate, influence the species composition of a plant community and the distribution of biomass. Temperature, moisture, carbon dioxide and oxygen availability influence the rates of chemical reactions and biological activity in ecosystem processes (Chapin, Matson and Vitousek 2011). When engineering and restoring ecosystems, it is also important to consider weather extremes (e.g. more frequent cyclones, intense rainfall and longer drought periods) from global warming impacts. Many terrestrial species have shifted their geographic ranges, seasonal activities and migration patterns (IPCC 2014), thus consideration should be given to species that are resilient to climate change.

The Project area has a climate which is characterised by a distinct wet season in the months of December, January and February, with monthly rainfall averages of greater than 100 mm and a distinct dry season between the months April through October with less than 50 mm mean monthly rainfall between these months. Evaporation rates are highest during the summer months, and lowest mid-year. In any given month, the average evaporation is greater than the average rainfall. Natural or induced climate related hazards such as severe storms, cyclones, floods, bushfires and droughts occur and pose risks which require management and climate change predictions show an anticipated increase of these events. A more detailed discussion of the Project area climate is at Chapter 4 – Climate.

11.3.1.1 Key Rehabilitation Considerations

- Engineering for stability and intense rainfall events in site stormwater controls;
- Seeding and vegetation cover to be in place prior to the wet season to reduce erosion risk and increase success of vegetation establishment; and
- Selection of species will include those that are most resilient to climate change.
11.3.2 Landscape and Landform

To effectively rehabilitate land, it is important to understand the catchment landscape, particularly the landscape processes of weathering and material movement as well as land use and the upstream and downstream ecosystem services. Weathering is fundamental to landscape evolution and topographic development and the development of soil, regoliths and weathering profiles (Turkington et al. 2015). Landscape processes cause spatial variation of soil moisture, fertility and rooting depth which drives the distribution of plant species and communities. Key landscape processes which must be considered in mining restoration are outlined in Table 11-1.

Table 11-1 Key landscape processes

<table>
<thead>
<tr>
<th>Process</th>
<th>Description</th>
<th>Relevance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Water and sediment movement process</td>
<td>The fluvial landscapes and the sediment will be transported from the mountains into the valleys then deltas.</td>
<td>▪ Altering this process and movement of sediment within the landscape can significantly change the downstream landscape; and ▪ Identify potential downstream impact areas if contamination released offsite.</td>
</tr>
<tr>
<td>Landscape evolution process</td>
<td>The topographically controlled redistribution of materials through gravitational force moving water and sediment downhill, landslides, soil creep.</td>
<td>▪ Controls over soil losses; ▪ Topography and slope influence erosion and deposition (Chapin, Matson and Vitousek 2011); ▪ Physical pathway by which materials move between ecosystems; and ▪ Understand how the rehabilitated site will behave over time.</td>
</tr>
<tr>
<td>Physical weathering process</td>
<td>The fracturing and breaking of rocks into smaller fragments caused by heat, freezing of water and expansion, salt crystal growth, wetting and drying, exfoliation.</td>
<td>▪ Understanding the local weathering pressures and processes at the site; ▪ Dissolution of saline content in rock and material overtime; and ▪ Stability and integrity risks of reformed areas.</td>
</tr>
<tr>
<td>Chemical weathering</td>
<td>Process through reactions (dissolution, redox reactions, reaction with water, oxygen or carbonic dissolution).</td>
<td>▪ Mining rehabilitation with waste rock management to avoid acid mine drainage; ▪ Soil salinity and toxicity; ▪ Soil sodicity and erosion; and ▪ Development of the soil profile and mineral composition.</td>
</tr>
</tbody>
</table>

These processes will be considered through the application of landform evolution modelling in revising the final landscape design. This will enable engineering of landform restoration to integrate into the surrounding landscape, protect long term stability, avoid detrimental impacts from weathering and obtain a functional landscape system.

Waste rock analysis presented in SEIS Chapter 8 – Waste Rock and Rejects indicated the risk of heavy metals leaching from waste rock is low and will have minimal impact on surface and groundwater. The waste rock was classified as non-acid forming (barren), with generally high acid neutralising capacity, and likely to remain pH neutral to alkaline following excavation. Therefore, dissolution of heavy metals in an acidic environment from physical and chemical weathering processes is unlikely to pose ongoing risks to rehabilitation success.

Sodicity of waste rock and coal reject composite samples, in the form of Exchangeable Sodium Potential (ESP: %), were very high (28.9% to 42.7%). Strongly sodic materials are likely to have structural stability problems related to potential dispersion. In addition to potential dispersion, sodic materials often have unbalanced nutrient ratios that can lead to macro-nutrient deficiencies.
11.3.2.1 Key Rehabilitation Considerations

- The Project is in an area subject to infrequent intense rainfalls, heat, and is also subject to high winds associated with cyclonic events. The landscape is highly fragmented from cattle grazing which increases the physical weathering of the soil surface;

- The region’s seasonality makes it prone to wind erosion, particularly during the dry season. Therefore, ground cover should be established prior to the dry season;

- Further minimisation of potential acid generation from waste rock because of physical and chemical weathering, through operational management by replacing areas of risk materials back in-pit and having long-term exposure of weathering to acid neutral materials within residual spoils; and

- Effective management of sodic waste materials back in-pit or within residual spoil areas where slope management and rehabilitation timeframes are key considerations.

11.3.3 Hydrology

Hydraulic regimes are driven by climatic precipitation and influence structural aspects of the ecosystem such as the floristic structure and plant species distribution through the soil moisture profile, infiltration for plant growth and biomass. They also influence the landscape structure through erosion rates, sediment movement and deposition and soil profile formation. The hydrology can also influence the functional aspects as water movement in the soil and exposed rocks can leach soluble heavy metals and contaminants and transport seeds and organisms into waterways and the downstream environment facilitating dispersal (Gurnell et al., 2008) and genetic diversity (Larsen et al., 2012).

11.3.3.1 Project

The Project is wholly contained within the Styx River Basin, comprising Styx River, Waverley and St Lawrence Creeks. The Styx Basin discharges to the Great Barrier Reef Marine Park (GBRMP) (refer Figure 11-1), which is listed as a World Heritage Area. The Project is bordered by two watercourses as defined under the Water Act 2000, namely Tooloombah Creek and Deep Creek (Figure 11-2). These creeks meet at a confluence downstream of the Project area to form the Styx River. The boundary of the Great Barrier Reef Coastal Marine Park is located approximately 10 km downstream of the ML area (General purpose zone), the marine National Park zone is located 40 km downstream of the ML area.

The Fitzroy Basin Association Natural Resource Management (NRM) body manages waters within the Styx Basin. Fitzroy Basin Association NRM body encompasses eight sub-catchments; Lower-Fitzroy, Isaac-Connors, Comet, Upper and Lower Dawson, Styx-Herbert, Water Park and Boyne-Calliope. Due to the NRM comprising an area over 152,000 km\(^2\), the region has been split into 192 Neighbourhood Catchments. The Project is located within the F3 Neighbourhood Catchment which is described as having a high sediment delivery ratio to the Great Barrier Reef with a low number of landholders within the basin (Fitzroy Basin Association 2015). Sediment in the Fitzroy Region is the most significant risk to the Great Barrier Reef, with an estimated 1.5 million tonnes of extra sediment deposited each year and 83% of the sediment coming from grazing land. It is estimated that the Styx Basin contributes 97,892 t per year. The load contributions from the Styx Basin are based on limited monitoring results. Cattle grazing is the dominant land use of the area (80%) and the basin contains 14% wetland area. Many of the wetlands are estuarine systems (8.8%) with approximately 187 lacustrine / palustrine wetlands (EHP 2017).

DATA SOURCE
QLD Spatial Catalogue (QSpatial), 2017
11.3.3.2 Key rehabilitation considerations

- The drainage diversions will be permanently established to a stable, vegetated and self-sustaining channel by final mine closure. As such, they will be retained following mine closure to ensure continued protection of downstream water quality values;
- Due to risk, albeit very minor, of saline drainage and the location of waste rock stockpiles to Tooloombah and Deep Creeks, permanent dams will capture potential acid rock drainage (ARD) or saline drainage required to protect water quality values in the Styx River;
- Risks to rehabilitation success from ARD to be managed at the outset during planning and operations through further analysis and strategic placement; and
- The design life of these dams will need to consider the post mine use and extended life span.

11.3.4 Geology, Soils and Root Zone Function

Geological processes and structure influence the landscape features and formation, groundwater movement and the physical and chemical properties of the geological rates of weathering, sediment movement and soil properties. In addition to the parent material, soil properties are also determined by climate, organisms, topography and time. Soil age and weathering influences the mineral composition through the solubility and leaching of various elements (Chapin, Matson and Vitousek 2011). The Project’s regional geology is located in an Early Cretaceous intra-cratonic sag basin. It probably developed by subsidence of the Strathmuir Synclinorium, an older feature containing Permian Bowen Basin strata (Geoscience Australia, 2008). The Styx Basin plunges to the north northwest, with an elongate shape bounded by the half graben fault to the east and onlapping the Permian Back Creek Group to the west (Arrow Energy, 2005; Waratah Coal, 2008), but the general dip of the Styx Coal Measures sequence is to the east.

Soil has physical, chemical and biological constituents that are essential components in the biogeochemical cycles of water, carbon, minerals and nutrients providing a foundation for vegetation communities. Physical properties such as soil bulk density, texture, structure and pore space influence soil water availability, root penetration, water storage and supply, porosity for transmission of liquids and gases and space for biota. The chemical constituents that influence species diversity and terrestrial primary productivity are nutrient availability, salinity and sodicity (Medinski et al., 2010) and mineralogy. Nutrient availability is impacted by soil pH (Wright 1992), decomposition and microbial activity, mineral weathering and dissolution (Leopold 2012).

Biological soil fauna (moss, algae, lichen, worms and fungi) provide decomposition functions which breakdown organic matter increasing the available nutrients (Voroney and Heck 2015) and releases of carbon to the atmosphere (Chapin, Matson and Vitousek 2011). Decomposition can occur through leaching of materials which are absorbed or react with mineral phase of soil, fragmentation through digestion from soil biota or chemical alteration from soil microbes (bacteria and fungi) (Chapin, Matson and Vitousek 2011). Decomposition also improves soil aggregate formation (van Leeuwen et al. 2011), water penetration, resistance to erosion, and other ecosystem services, including water quality, limiting invasive species, and increasing disease prevention. Soil microorganisms produce plant growth stimulating substances and can immobilize heavy metals in the soil. Mining rehabilitation requires the understanding of these processes to engineer the soil profile through the stimulation of bio-weathering, promotion of nutrient cycling and addition of soil biota to support the vegetation community being restored.

The Project area contains several different soil types; Vertosols, Sodosols, Dermosols, Kandosols and Rudosols. The soil properties and land support capabilities are outlined in Chapter 5 – Land. Most soil types have few physical root limitations; however, the clay sodic B horizon of the Sodosol
will restrict root growth. Within the Central Queensland Coal mine area, soil salinity is generally low except for some salt build up found in the B horizons of the Sodosols. The Sodosols are also dispersive and prone to erosion and soil structural decline, if disturbed. For other soil types in the Central Queensland mine area, the non-sodic, minimal dispersive soils within the mine area is suited to pastoral land use. The baseline soil fertility and organic carbon levels within the Project area is low to moderate and most are suitable for pasture production and beef cattle grazing.

11.3.4.1 Key Rehabilitation Considerations

- Loss of topsoil fertility and viability from storage of topsoil over extended time periods;
- Soil pH should be used as an indicator as Kandosols have potential to create aluminium toxicity if conditions become acidic; however, assessment shows soils to be currently neutral to alkaline;
- Vertosols and Sodosols have tendencies to pose secondary salinity problems which need to be addressed within the rehabilitation; and
- Sodic soils have severe erosion potential on slopes in high intensity rainfall and as such, slopes require quick establishment of vegetative cover.

11.3.5 Management of Sodic or Dispersive Soils

Sodicity of waste rock and coal reject composite samples, in the form of Exchangeable Sodium Potential (ESP: %), were very high (28.9% to 42.7%) (see Chapter 8 - Waste Rock and Rejects). Strongly sodic materials are likely to have structural stability problems related to potential dispersion. In addition to potential dispersion, sodic materials often have unbalanced nutrient ratios that can lead to macro-nutrient deficiencies. Hence, to promote vegetation growth during rehabilitation.

Sodic and dispersive materials will be identified, selectively handled and placed within the core of waste rock stockpiles away from final surfaces or returned to voids during mining. Where sodic waste materials may be required for use as an additional topsoil, prior treat would likely be required. The most effective means to ameliorate against sodicity during rehabilitation works is to apply and incorporate gypsum; and / or apply and incorporate an organic amendment e.g. biosolids, composted manure, mulch, straw, etc. Given the volumes involved, these approaches are unlikely to be effective. As such, the following management practices will be employed:

- Test spoil ahead of mining and rehabilitation. The most relevant test is exch. Na %. The approximate threshold levels are:
  - Very low <4%
  - Low 5-8%
  - Moderate 9-12%
  - High 13-15%
  - Very High >15%

Other tests that can be used to determine sodicity are Dispersion % or the Emerson Aggregate Test;

- Selectively bury high to very high exch. Na% (sodic) spoil (if practicable);
Ensure moderately sodic material is top dressed with topsoil; and

Low and very low sodic material can be sown with native trees and shrubs without topsoil provided that the spoil has a pH of > 4.5 and < 8.5 and is non-saline. The spoil must be coarsely ripped i.e. rough seedbed preparation with distinct furrows (not smooth).

11.3.6 Terrestrial Ecology

Vegetation communities are composed of many co-existing species. Dominant vegetation species provide canopy structure influencing light infiltration and thus the substructure and species present within the community. Ecological restoration must consider the nutrient and water needs of the species, the synergistically or antagonistically co-existence of plant species and plant interactions with microbes, soil fauna and animals to restore ecosystem function.

Framework species, functional groups and keystone species play a significant role in restoring ecosystem function (van Andel, Grootjans and Aronson 2012). Framework species can be introduced first as they have functional traits of fast growth and fruit / food production, high survival and high tolerance. These species can play a vital role in primary succession providing capacity to deal with the highly-disturbed environment with potentially organic poor (low nitrogen, low water holding capacity) soils (Chapin, Matson and Vitousek 2011). Plant root physiology and rooting depth must be considered, especially in areas of buried sodic or saline material or capped contaminates.

Ecosystem function relates to primary production, decomposition and nutrient cycling. Representation of species within these functional groups facilitates continued development and / or stability of the system (van Andel, Grootjans and Aronson 2012). Nitrogen-fixing species provide nutrient cycling function by accessing nitrogen through symbiotic bacterium relations facilitating the establishment and growth of later successional species. This function is important in areas of low nitrogen and minimal soil development (Chapin, Matson and Vitousek 2011). Keystone species are plants or animals that play a unique and crucial role in the way an ecosystem functions (National Geographic Society 2016) and can be used as indicators of success. Biotic ecosystem structure is shaped by the food chain and the loss of keystone species may alter the ecosystem structure.

The Project area occurs within the Brigalow Belt bioregion. Dominant vegetation communities include open forests (dominated by Brigalow (Acacia harpophylla), BlackGidyea (A. argyrodon), Gidgee (A. cambagei), Lancewood (A. shirleyi), Dawson River Blackbutt (Eucalyptus cambageana), River Red Gum (E. camaldulensis), Forest Red Gum (E. tereticornis)), woodlands (dominated by Silver-leaved Ironbark (Eucalyptus melanophloia), Narrow-leaved Ironbark (E. crebra), Poplar Box (E. populnea), Brown’s Box (E. brownie), E. persistens, Mountain Coolibah (E. orgadophila), Coolibah (E. coolabah), River Red Gum and Forest Red Gum) and small patches of semi-evergreen vine thicket.

The majority of the Project area occurs in the Marlborough Plains subregion (BRB14) of the Brigalow Belt bioregion. The Marlborough Plains subregion is a characteristically undulating to hilly subregion with a complex geology. The subregion is dominated by alluvial plains and colluvial slopes, usually supporting woodlands characterised by Poplar Gum (Eucalyptus platyphylia), Ghost Gum (Corymbia dallasiana), Forest Red Gum and Tea-tree (Melaleuca spp.) with low rises supporting Narrow-Leaved Ironbark. Clearing over the past 150 years has resulted in a highly-fragmented landscape with vegetation generally confined to rockier hilly areas, linear strips of roadside vegetation, riparian vegetation and relatively small isolated remnants.

Vegetation within the mine area, haul road and TLF is generally representative of the Marlborough Plains subregion comprising:
- Large areas of heavily disturbed habitats that have previously undergone significant clearing for cattle production; and
- Smaller pockets of fragmented closed canopy vegetation largely associated with creek systems and rocky areas.

11.3.6.1 **Key Rehabilitation Considerations**

- Restoration of the current vegetated areas would protect long-term values of Commonwealth and State significant vegetation;
- Protected or threatened species likely in the Project area include Greater Glider (*Petauroides volans*), Squatter Pigeon (*Geophaps scripta*), Ornamental Snake (*Denisonia maculate*) and Koala (*Phascolarctos cinereus*). In consideration vegetation reestablishment outcomes, potential food and habitat needs of these species is included; and
- Framework species of existing Regional Ecosystems onsite to be used in seed mix and flora food and habitat species for keystones species.

11.4 **Ecosystem Services**

Ecosystem services are ecosystem functions or groups of functions with utility for human society (Muller, Fohrer and Chicharo 2015). The Millennium Ecosystem Assessment (2005) defines four categories: supporting services, provisioning services, regulating services and cultural services, as shown in Figure 11-3.

![Source: Bouma and Beukering 2015](image)

**Figure 11-3 Ecosystem services**

The sustainability of ecosystem services is paramount as human well-being ultimately depends on the health of ecosystems (Bouma and Beukering 2015). Restoration of ecosystems should consider safeguarding these services for future generations. This requires high plant diversity and reduced human stressor impacts.

Several regulating ecosystem services are provided by this ecosystem including local climate, air quality, water flow regulation, water purification, nutrient regulation, erosion regulation and natural hazard protection.
11.5 Current Land Use and Post Mining Land Use

The current land use in the Project area is predominantly grazing with limited areas of native remnant vegetation. Investigations of land use following industry classification methods have been undertaken to define the current land use. This information has in turn allowed for the determination of the final land use, post-mining activities, to allow the development of potential rehabilitation strategies to minimise potential environmental impacts.

Central Queensland Coal intends to manage its operations and conduct decommissioning and rehabilitation activities to ensure that the land disturbed is returned to land suitable for the continued natural regeneration of land undisturbed by mining activities or land that have been rehabilitated to meet conservation objectives. A small section of the Mamelon property, located at the southern extent of the ML boundary, will continue to be set aside for grazing.

11.6 Rehabilitation Framework

The Project is not expected to be decommissioned for approximately 20 years or following depletion of the target coal resource. Progressive rehabilitation is proposed to be carried out as operations progress rather than taking place as a large operation once mining is complete. Rehabilitation of the mine infrastructure area, haul road and TLF will of take place once mining is completed and plant and structures have been decommissioned.

The Rehabilitation Framework will be developed and evolve over time to reflect changing regulatory requirements, community values, and lessons learned onsite or at other mines. A RMP will be developed based on objectives and goals that seek to provide predetermined land uses for the different land units (domains) of the mine (see Section 11.8). Success criteria for each of these domains will be established which will need to be met to demonstrate rehabilitation. The rehabilitation works will be designed within the constraints of the site’s conditions (e.g. the climate, topography and soil / rock types) as well as the mining plan and schedule.

11.7 Rehabilitation Objectives and Performance Criteria

The Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland series (Department of Minerals and Energy (DME) 1995) and Guideline EM1122, Rehabilitation Requirements for Mining Resource Activities (EHP 2014) (the Guideline) state four general rehabilitation goals. These require rehabilitation of areas disturbed by mining to result in site conditions that are:

- Safe to humans and wildlife;
- Non-polluting;
- Stable; and
- Able to sustain an agreed post-mining land use.

Central Queensland Coal will seek to achieve the following overarching rehabilitation and decommissioning goals to address the general rehabilitation goals as nominated in the Guideline by:

- Providing landforms with the same or similar land use capabilities and / or suitability prior to the disturbance, unless other beneficial land uses are pre-determined and agreed with key stakeholders (post-mining land owners, managers and relevant regulators);
• Rehabilitation of disturbed land so that it presents a negligible safety or environmental risk in terms of stability;

• Providing land that is self-sustaining to agriculture or ecosystem processes where maintenance requirements are negligible and consistent with an agreed post-mining land use; and

• Maintaining the water quality and quantity acceptable for existing and future users within or surrounding the site.

These overarching goals will provide for a post-mining site that is physically safe to human and animals, geotechnically stable, non-polluting and capable of sustaining the agreed land uses. These goals are consistent with the principles of ESD as required by the EP Act.

11.7.1 Short and Long-term Rehabilitation Goals

The above overarching rehabilitation goals can be defined into short-term and long-term goals as outlined in the following sections.

11.7.1.1 Short-term Goals

Short-term rehabilitation goals for the mine are to:

• Minimise clearing and vegetation disturbance consistent with operational requirements;

• Schedule operations including overburden and interburden emplacement and shaping, and revegetation to minimise visual exposure;

• Rehabilitate areas of disturbance no longer required for mining related operations;

• Apply soil (topsoil / subsoil) to the final landform based on material availability and post-mining land use;

• Stabilise all earthworks, drainage lines and disturbed areas to minimise erosion and sedimentation; and

• Control vermin, feral animals and noxious weeds.

11.7.1.2 Long-term Goals

The overall long-term goal is to rehabilitate the land to a low maintenance, stable and safe landform that blends with the surrounding topography and maximises the return of agricultural land suitability comparable to pre-mining levels. These long-term goals will be met by measures including:

• Post-mining land suitability for natural regeneration and sustainable rehabilitation with a small section set aside for grazing;

• Providing habitat for fauna and corridors for fauna movement within the final landform;

• Preservation of downstream water quality for ecological and existing beneficial uses;

• Establishment of a low maintenance, geotechnically stable landform commensurate with nature conservation land uses;

• Blending the created landforms to appear as a natural extension of the surrounding environment; and

• Monitoring rehabilitation success in terms of physical and biological parameters.
A Mine Closure Plan (MCP) will be prepared outlining the specific operational activities required to complete the rehabilitation and decommissioning of the Project. The MCP will include monitoring and management of:

- Wastewater collection systems and treatment systems;
- Groundwater quality and levels;
- Surface water quality and flows;
- Seepage rates;
- Erosion rates;
- Integrity and stability of slopes and ramps; and
- Health and resilience of vegetation cover.

Should the guidelines be issued for the PRCP, this will be prepared in place of a MCP.

11.8 Mine Domains

Rehabilitation goals and strategies for the Project were nominated for individual land management units or domains within EIS Chapter 11 – Rehabilitation and Decommissioning. Discrete elements to be rehabilitated within each domain were described. The following section provides an updated description, based on changes to the mine design completed since the release of the EIS.

Since the EIS was released the decision was confirmed that most of the Mamelon Property, including most of the ML, will be destocked and suitable areas outside of the mining disturbance area will be established as environmental offsets. A small area already cleared for grazing activity at the southern end of the ML may be retained as that land use; however, this will be confirmed through the finalisation of the Offset Plan. The creeklines will also be fenced off to enable natural regeneration within the riparian areas. The following section also reflects the goal to return the area post-mining to a condition consistent with established offset and biodiversity programs.
11.8.1 Updated Mine Domains

Rehabilitation goals and strategies are nominated for individual land management units or domains with discrete elements to be rehabilitated within each domain. The mine site has been divided into three major management domains and sub-domains. These are provided in Table 11-2 along with the maximum surface area for each domain and shown in Figure 11-4.

11.9 Proposed Rehabilitation Strategy

EIS Section 11.9.1 stated the Post-Mining Completion Works Years 18 – 20 Program would include the rehabilitation of remaining voids. As there will no longer be any retained voids, an updated Post-Mining Completion Works Years 18 – 20 Program has been developed to reflect this.

As all voids will now be infilled, there is a change in the footprint of Waste Rock Stockpile 2 and Waste Rock Stockpile 1 (now Waste Rock Stockpile 1a and 1b). Consequently, the final landform discussion and figures at EIS Section 11.9.1 have been updated to reflect these changes.

Modelling of the final rehabilitation landforms will be undertaken in developing the PRCP. This will include modelling potential risks of adverse impacts from any proposed retained water storages and retained levees or bunds. The PRCP will also consider potential for adverse impacts associated with flooding post mining operation, along the long-term management of any AMD and / or saline drainage. The following sections provide an updated Progressive Rehabilitation Program which will be further developed in the PRCP.

11.9.1 Progressive Rehabilitation Program

Progressive rehabilitation will apply to the open cuts and waste rock stockpiles. The main features of the progressive rehabilitation process are:

- Constructing a stable landform for all disturbed areas;
- Topsoil spreading across available reshaped areas;
- Contour ripping immediately after topsoil placement to control erosion;
- Revegetation with an appropriate seed mix prior to the wet season; and
- Management of rainfall and runoff from the rehabilitated landform in sediment dams.

The proposed mine life is 20 years including the final rehabilitation and mine closure period. The indicative program for progressive rehabilitation is described below. Progressive rehabilitation will occur in accordance with the Plan of Operations, until the requirement to prepare a PRCP comes into force. The Plan of Operations will identify areas to be rehabilitated and refer to the RMP for specific rehabilitation details for each domain and desired post-rehabilitation land use. The proposed rehabilitation program is summarised below.

Construction  - Infrastructure construction to commence in conjunction with mining the Box Cut. All works areas to be cleared and grubbed with disposal of vegetation. Topsoil to be stripped and separately stockpiled for future use. Primary sediment controls such as dams to be constructed in this phase.
Operational Years 2 to 19 – Waste rock stockpiles to be utilised initially during pit development for overburden and for coal rejects (filter press tailings – refer EIS Chapter 8 – Waste Rock and Rejects for further disposal details). Waste rock stockpiles will be reshaped and contoured, stabilised, topsoiled and seeded to minimise potential erosion. Once in-pit dumping commences, waste rock stockpiles will be shaped and used as cells for rejects. Reshaping and stabilisation of in-pit dumps will continue through operations. Progressive rehabilitation, including reshaping, topsoiling and seeding will be undertaken through the operational period.

Post-mining Completion Works Years 18 – 20 - All voids will be in-filled, shaped, topsoiled and seeded. Once voids are in-filled, remaining out of pit waste rock stockpiles will be rehabilitated. Mine infrastructure will be decommissioned and dismantled for removal from site with the individual locations rehabilitated accordingly. Dams and access roads will remain for future beneficial use or decommissioned. Rehabilitated areas will be monitored and if necessary, reworked to achieve the required completion criteria.

The aim of progressive rehabilitation is to minimise the amount of land disturbed at any one time. The indicative program for progressive rehabilitation is shown as schematics in Figure 11-5 and Figure 11-11. The progressive rehabilitation contours and final landforms are shown in Figure 11-7 to Figure 11-11. These show rehabilitation at various stages, including ex-pit waste rock stockpiles and in-pit dumping where rehabilitation has been completed in year 3, 9, 18 and the final landform. The final landform of the rehabilitated pits and waste rock stockpiles lie outside the post mining 0.1% Average Exceedance Probability (AEP) flooding (Figure 11-12). Progressive rehabilitation will also include the rehabilitation of any areas disturbed during construction that are not required for ongoing operations.

11.9.2 Landforming

The cumulative volume of excavated waste from open cut activities is expected to include approximately 755 Million bank cubic metres (Mbcm) consisting of waste rock, subsoils and fines from the CHPPs. As operations commence, waste rock from the open cuts will initially be stored in the ex-pit waste rock stockpiles. As mining in the open cuts progress, the stored waste rock will be backfilled in-pit as part of the progressive rehabilitation. As such it is not anticipated that extensive rehabilitation will be required of the waste rock stockpile areas over and above re-seeding. This will; however, be assessed as mining progresses. All dry filter press tailings have final disposal within the pit.

Expired pit areas will have the reject waste and overburden returned and will be profiled to the final desired landform specifications. Subsoil and topsoil will be replaced on the profiled landform in the reverse order to which it was stripped from the open cut domains; that is the subsoil is placed on top of the overburden and the topsoil on top of the subsoil at an appropriate thickness.

Before the topsoil is spread, the profiled landform will be scarified parallel to the contour to a nominal depth of 50 to 100 millimetres (mm) to break up any hard setting surfaces and prevent lamination of the topsoil and profiled landform. Dependant of the quantities originally recovered, topsoil will be spread to a nominal depth of between 100 to 150 mm where possible.

Where required, contour banks will be progressively installed to minimise rill erosion and direct water off the profiled landform to either a stable surface or dedicated stabilised drainage paths or flumes constructed on the final landform. The heights and depths of these contour banks will be determined through ongoing landform design. At the finalisation of this process a pre-vegetation landform will have been constructed. Finalised landforms will initially be sown with either a cover crop or perennial native vegetation. Areas intended for ongoing nature conservation will be over sown with non-invasive perennial grasses as an interim measure until the area becomes available for inclusion in the ongoing revegetation program.

11.9.3 Erosion and Sediment Control

The erosion potential for all permanent and temporary landforms associated with the Project will be assessed and will focus on erosion and stability effects for all disturbed areas, including areas disturbed or exposed during decommissioning and rehabilitation. The methods to prevent or control erosion will have regard to the long-term stability of the land, preventing soil loss and preventing the degradation of waterways.

Erosion and sediment control measures (see Chapter 5 – Land) will be like those applied during construction and during operations and will be outlined in the Project’s Project Erosion and Sediment Control Plan (ESCP). The ESCP will be developed by a suitably qualified person in accordance with relevant legislation and guidelines. This will relate to the whole Project area and identify the risk of erosion and sedimentation within each area of the Project based on the soil type present.

Runoff from rehabilitated areas will collect in contour drains and collection drains, from where it will be directed to sediment dams and settling ponds to remove suspended sediment prior to draining from site. These drains and ponds will be maintained to ensure their proper functioning.
11.9.4 Soil Management

Topsoils and subsoils will be stripped, handled and stored to prevent excessive soil deterioration. An inventory of available soils will be maintained to ensure adequate materials are available for planned rehabilitation activities. General soil management will include the following measures.

Topsoil Stripping

- Prior to stripping, all vegetation would be progressively cleared to the minimum extent required for the impending future works;
- Supervisors and earthmoving plant operators will be trained to visually identify the topsoil layers to ensure that stripping operations are conducted in accordance with stripping plans and in situ soil conditions; and
- Care will be taken to ensure soil moisture conditions are appropriate for stripping and stockpiling, for example the moisture content of the topsoil material is not too dry or too wet.

Stockpiling

- Material that has been stockpiled for reuse will be protected from excessive disturbance or traffic, and stockpiled away from drainage lines;
- Drainage will be constructed to manage or divert surface water flows around stockpiles and maintained to ensure proper functioning;
- Topsoil stockpiles will be formed in low mounds with a height up to three metres and subsoil stockpiles up to six metres. Long-term stockpiles (present for greater than six months) will be deep ripped and provided with a vegetative cover to maintain the soil health, maintain biological activity and minimise erosion potential. Stockpiled material will be constructed with batters or gradients of 1:4 wherever possible; and
- Weed and pests will be monitored and controlled as required.

Respreading

- Movement and handling from stockpiles to be conducted to minimise structural degradation such as compaction;
- Selective placement of more erodible soils on flatter areas as opposed to steeper slopes to minimise erosion potential;
- Respreading of soil in even layers at a thickness appropriate for the intended final land use;
- Avoidance of soil lamination through contour ripping to encourage soil keying, water infiltration and minimise runoff;
- Reseeding and revegetation as soon possible after respreading to establish vegetation cover;
- Installation of slope drainage control to limit slope lengths and runoff velocities; and
- Installation of collection drains and catch dams to collect runoff and remove suspended sediment.
11.9.5 Revegetation

Revegetation activities will typically commence at the completion of land forming, such as, reshaping, re-topsoiling and drainage works. The timing of these works will ideally be scheduled to enable a preferred seasonal sowing of pasture or tree seed. Where surfaces have been prepared, the nominated revegetation specification for tree, shrub and pasture species, will be sown using seed stock or planted depending on the species, slope gradients and final land use. Rehabilitation will utilise locally relevant tree and shrub species at a density and richness consistent with the desired post-mine landform. Plant selection for areas to be returned to a bushland landform will be based on the following criteria:

- The species will successfully establish on the available growth medium;
- The species will bind the soil; and
- The species diversity will result in a variety of structure and food and habitat resources.

Native flora used for rehabilitation will ideally be endemic and will be established through a combination of direct seeding or planting of tube stock from local propagules. Seed will be collected from site where possible and treated if necessary to ensure it is adapted to environmental conditions in the area. Tree and shrub establishment onsite will be dominated by the direct seeding method, currently being used at most coal mines in the Bowen Basin.

An initial tree and shrub mix that could be used for rehabilitation is provided in Table 11-4 and is based on the current suite of flora species found in the Project area. The final species mix will depend on the final agreed RMP and will be reviewed periodically depending on changes in best practice, technology and rehabilitation monitoring results.

</tbody>
</table>
A combination of native and introduced pasture species will be used to ensure the establishment of a groundcover and reduce the likelihood of erosion. Legumes may also be selected to assist in the supply of bio-available nitrogen to the soil. If the use of introduced grasses and/or legumes is deemed necessary for erosion control in the bushland areas, pasture seed and fertilizer will be applied at a lower rate than for pasture outcomes to reduce competition with tree seed and/or seedlings.

### 11.9.6 Undisturbed Land

Land not impacted by mining activities will be retained for natural regeneration and a small area on Mamelon, but outside of the ML, will be set aside for cattle grazing purposes. Land not impacted but made inaccessible by mining activities will be allowed to naturally regenerate free of grazing.

### 11.9.7 Mine Infrastructure Area

Following decommissioning, most infrastructure areas will be returned to the pre-mining landform or alternatively bench cuts will be removed and steep grades reduced and the landform returned to a profile similar to current landforms in the region. Where beneficial use of an area can be gained, such as access tracks, roads, hardstand or TLF facility, the final landform use will be negotiated and accepted in writing with the underlying landholder and DES.

Building end use will be assessed at the time of Project closure, as alternative uses may be available. It is likely, however, that the main administration building, workshop, CHPP and fixed plant (conveyors and gantries, transfer points, thickener tank, coarse reject hopper, vehicle wash, etc.) will be dismantled or demolished and removed from the site. Where infrastructure is removed, the footprint area will be assessed and where required, reworked to facilitate the appropriate drainage of surface runoff from the site.

Where required, potentially hazardous locations will be decommissioned and/or rehabilitated to an acceptable level to prevent negative environmental impacts. This may require sumps to be de-watered and the excess coal removed prior to the commencement of demolition. In addition, all items of equipment will be de-oiled, degassed, depressurised and isolated, and all hazardous materials removed from the site as per legislative requirements.

Appropriate surface water management structures (contour banks, drains and settlement ponds) will be constructed as required to minimise potential erosion of the decommissioned and rehabilitated area.
11.9.7.1 Roads and Hardstands

Where no beneficial long-term use can be provided to the final land use, road furniture and fittings will be removed from site for recycling or disposal. The roads, car parks and hardstand areas will be ripped, topsoiled and rehabilitated. Several of the internal and haul roads may be retained for use by future landowners. Several additional haul roads will also be temporarily retained following rehabilitation as access roads for rehabilitation monitoring purposes. Roads and hardstands to remain after mine closure will be determined in consultation with DES. For those roads to be left operational, either permanently or temporarily, erosion and sediment controls will be employed to prevent and minimise sediment entering waterways.

Most haul roads and access tracks across the Project area requiring decommissioning may be highly compacted and require a combination of rehabilitation techniques such as deep ripping, profiling, topsoiling and seeding. Contaminated, carbonaceous or unsuitable material will be removed from the haul roads and hardstand surfaces and disposed of to the low wall area and incorporated into the rehabilitation of those areas. Reshaping of roads and access tracks will be undertaken to reflect the surrounding landforms. Where not required for beneficial long-term use, creek crossings will be removed and the pre-existing drainage lines re-established. As required, drainage will be constructed where necessary. Roadside markers (tyres and guideposts) and redundant signage will also be removed from within the area once mine closure activities within the pit area have been completed.

11.9.7.2 Train Loadout Facility

The infrastructure associated with the TLF, including the rail loop, rail spur, rails and sleepers, will be removed at the end of the Project life, unless approved for use by another party. Any contaminated areas will require onsite remediation or encapsulation onsite to prevent the release of contaminants.

11.9.8 Water Infrastructure

Where no beneficial long-term use can be provided to the final land use, water storage dams will be decommissioned and rehabilitated. If not retained as water storages, water storage dams will be rehabilitated and returned to land consistent with desired rehabilitation and conservation objectives. The rehabilitation process may require dewatering, removal of any sediments and embankments, and the re-establishment of original drainage paths. Rehabilitation techniques may include a combination of re-profiling, topsoiling and seeding. If water infrastructure is to be retained onsite, then this will occur following written agreement of the underlying landholder.

Rehabilitation may vary depending on the storage history during mine operations. Dams that have contained saline water may require additional remediation. This may require the membrane liner, if previously installed in the dam, to be removed. Any saline material inside the dam will be removed during rehabilitation and disposed of by appropriate methods, in accordance with the management of saline overburden material. Removal will either be through evaporation or, given the existing groundwater is already relatively saline, reinjection of the saline water. Alternatively, saline sediment will be capped using an inert clay layer and salt tolerant vegetation used to provide new plant cover. Dams collecting potentially contaminated runoff, for example from waste rock stockpiles, will be retained to control for any long-term pollution.

11.9.9 Open Pits

This section is no longer relevant to the EIS as there will be no retained voids and Open Cut 4 no longer exists within the mine plan.
11.9.10 Waste Rock Stockpiles

Noting the changes to the footprint of Waste Rock Stockpile 1 and Waste Rock Stockpile 2 an updated rehabilitation program has been developed. The following sections provide an updated discussion regarding the rehabilitation of Waste Rock Stockpiles 1a and 1b, and Waste Rock Stockpile 2.

The waste rock stockpiles will be designed, constructed and operated to enable progressive rehabilitation during operations with the final landform objectives in mind. Thus, the waste rock stockpiles will be managed to prevent pollution, be stable, safe and support the final land use both during operations and in the longer term to ensure post-closure objectives will continue to meet regulatory requirements.

Optimisation of the mine plan has been undertaken such that there will be no retained voids. Consequently, the mineral waste volumes reporting to waste rock stockpiles and the final landform described in the EIS have been updated.

The location of the waste rock stockpiles has been determined considering the presence and location of sensitive environmental receptors, including Deep Creek and Tooloombah Creek and Endangered and Of Concern Regional Ecosystems. The selected locations have also been selected to maximise the use of already disturbed land to minimise the clearance of remnant vegetation.

It is estimated that 755 Mbcm will report to the three ex-pit waste rock stockpiles and two open cut pits. The updated waste schedule is discussed in detail in SEIS Chapter 3 – Description of the Project. The size of the final area occupied by Waste Rock Stockpile 2 (servicing Open Cut 2) and Waste Rock Stockpile 1a (servicing Open Cut 1) will be 74 ha and 17.24 ha respectively. There will be no retained ex-pit overburden material associated with Waste Rock Stockpile 1b as the total volume of material will be returned to the void in Open Cut 1.

Geotechnical, climate, surface water and groundwater monitoring throughout the construction and operation of the Project will be used to evaluate the condition of the waste rock stockpiles and quantify their environmental risks. This information will then be used to determine the requirements for rehabilitation and closure control measures.

The stability of the waste rock stockpiles will be assessed based on the nature of: foundation materials, fill materials, and capping materials. The assessment will consider short-term, long-term and extreme conditions and meet the requirements of the Assessment and Management of Acid Drainage guideline of the Technical Guidelines for the Environmental Management of Exploration and Mining in Queensland series (DME, 1995).

Surface water flows will be prevented by capping using a low permeability material (i.e. clay), compacted and graded to limit stability issues which primarily result from water ingress and assist with directional precipitation runoff. Grading would be 2% and grade away from the crest. Side slopes would be designed to have 5% slopes. Contour grooving, channel linings, surface armour and drop structures on slopes will prevent long watercourse runs and minimise slope erosion. Certification will be obtained by Central Queensland Coal that slopes are stable in the long term and erosion rates are no greater than at comparable reference sites. To assist with rehabilitation soils with low sodic values will be stockpiled separately and used in the final stages of waste rock stockpile rehabilitation.

All dams receiving runoff from the waste rock stockpiles will retained to collect any fugitive sediment and prevent any contaminated water from entering surrounding watercourses. These dams would not overflow to surrounding watercourses. Groundwater and surface water monitoring would continue over a five-year monitoring period to demonstrate no pollution is occurring prior
to relinquishment of the mining lease. Water quality levels would be required to meet the Queensland Water Quality Guidelines 2009 (EHP 2009) and Environmental Protection Policy (Water) 2009 limits to be deemed ‘non-polluting’.

The waste rock stockpiles will necessarily result in a higher landform than that which existed before mining, although given the landform is already hilly it will not be out of character with the surroundings. Indeed, slopes of >5% are found within the existing mine area. Topsoil will be re-spread according to required depths and vegetation sown to establish cover comparable to reference sites. Soil characteristics will be measured \textit{in situ} to confirm levels of surface roughness, aggregate stability and surface conditions as defined in the Australian Soil and Land Survey Handbook. If there is an issue of saline or sodic materials then gypsum will be obtained from a certified supplier and added to the land, or into the waste rock stockpiles during operations.

Vegetation cover will be provided to not only assist with erosion control but to provide for the natural regeneration of native vegetation. Vegetation completion criteria will be measured based on achieving at least 70% cover as required by Eyre \textit{et al.}, 2015.

11.9.11 Pest and Weed Management

Weed species have the potential to negatively impact rehabilitation activities and have a major impact on both native vegetation and grazing. Fifty-three introduced weed species of which ten are classified as Restricted Matters under the Biosecurity Act 2014 (Biosecurity Act) and five declared as weeds of national significance were recorded within or surrounding the Project area (see Chapter 5 – Land, Chapter 14 – Terrestrial Ecology and Chapter 17 – Biosecurity for full details). Weed management will be a critical component of mine rehabilitation and will be conducted in conjunction with broader council and community weed management strategies where practical.

Weed control will be undertaken in a manner that minimises soil disturbance. Declared weeds will be controlled in accordance with the Biosecurity Act. A Land Use Management Plan will be developed and will incorporate a combination of control measures including:

- Herbicide spraying or scalping of weeds off soil stockpiles;
- Washdown and cleaning of high risk equipment prior to entering the site; and
- Monitoring and control of existing weed populations over the mine life.

11.9.12 Contaminated Land

Pursuant to the EP Act, an activity that will, or has the potential to, release contaminants into the environment and which may cause environmental harm is defined as an Environmentally Relevant Activity (ERA). In accordance with the Environmental Protection Regulation 2008 (EP Regulation) (Schedule 6, Item 5), the development will be a site-specific EA mining project for the mining of black coal. The activities associated with the Project will require a number of ERAs (as prescribed in Schedule 2, EP Regulation). The EA is an integrated authority that allows for the carrying out of multiple ERAs that are part of a project, as such all ERAs must be listed and described in the EIS for inclusion in the EA. The EA is expected to provide approval conditions for each of the required ERAs.

The Project has the potential to involve two ERAs applicable to the construction and operational stages. These ERAs are:

- ERA 8 (1)(a) Chemical Storage (see Chapter 21 – Hazard and Risk); and
- ERA 31 (1) Mineral Processing (see Chapter 3 – Description of the Project).
As such, soil will be assessed for contamination at the following potential locations:

- Mine infrastructure area (fuel and chemical storages, belt filter press processing area); and
- Soil profile under the ex-pit waste storage area after material is returned to in-pit.

A risk assessment of these activities suggested that potential impacts can be remediated with current common contaminated land practices. In addition, these potential impacts were assessed as having relatively low residual risk following the adoption of mitigation measures. The handling of hazardous materials and dangerous goods and the associated waste management strategies are discussed in separate chapters. Mitigation or control strategies will be included in either the construction or operational Environmental Management Plan.

Onsite records will be maintained regarding any activities or incidents that have the potential to result in land contamination. An inventory will also be maintained that contains information on storage locations, personnel training and disposal procedures for all chemicals, fuel and other potential contaminants used onsite.

Finances will be set aside to rehabilitate the land in the unlikely event of land contamination. Contaminated land, should it result from the Project activities, will be rehabilitated as per the regulatory conditions and by best practices at the time of mine closure to ensure the land is suitable for its final land use. Measures to minimise the risk of spills or spread of any contamination during decommissioning and rehabilitation will be implemented including, for example: identification of risk areas, appropriate investigation of contamination risk, isolation and removal or rehabilitation of land.

**11.9.12.1 Development of Specific Management Plans**

The development and statutory approval of all management plans discussed above will take place ahead of any construction or operation works onsite, as appropriate, and in consultation with DES. These plans will outline in detail how management, rehabilitation and mitigation measures will be implemented across the site. If an accelerated closure process is required, for example because of environmental, safety, economic or other external pressures, these plans will be adaptable to account for such a scenario.

**11.10 Qualitative Risk Assessment**

The deficiency to achieve rehabilitation goals may have the potential to cause, or may result in, adverse environmental impacts. The identification of impacts that could eventuate is critical to the selection of appropriate rehabilitation objectives or corrective action. During the detail design of the Project, prior to construction, the level of risk associated of not achieving rehabilitation goals will be determined using a Hazard Identification Matrix. This matrix will assess the likelihood and consequences to define a risk ranking.

The objectives of the risk assessment are to:

- Identify activities or outcomes that have the potential to adversely affect the local environment;
- Qualitatively evaluate and categorise each risk item;
- Assess whether risk issues can be managed by environmental protection measures; and
- Qualitatively evaluate residual risk with implementation of measures.
For each rehabilitation goal within the risk register there is a stated:

- Goal, objectives and performance criteria;
- Risk analysis negative impact occurring;
- Control measures to be implemented to meet management objectives / goals and performance; and
- Risk analysis of residual risk following the implementation of control measures.

Review and refinement of residual risk can be assessed and determined during the monitoring and implementation of the rehabilitation.

In line with the State government framework the rehabilitation process will use monitoring, targeted research and completion criteria to demonstrate ultimate success is shown in Figure 11-13. Within each rehabilitation stage, specific indicators will be monitored to determine and demonstrate the site has satisfied the completion criteria agreed between Central Queensland Coal and the administering authority.

Rehabilitation indicators are used to monitor the trending of ecological process towards the rehabilitation objectives, allowing early identification of issues requiring intervention and remedial actions. Indicators are used to demonstrate measurable effectiveness of the completion criteria to comply with community and regulatory expectations. The proposed completion criteria are approved and conditioned within the EA for the mine and provide the assessment benchmark for surrendering the EA and discharging the financial assurance (EHP 2014). The rehabilitation indicators and completion criteria have been developed in line with the legislative framework, standards and relevant industry codes of practice.

![Figure 11-13 Process of determining rehabilitation progress and success](image)

Monitoring and reviewing of the implementation of the rehabilitation strategies as discussed previously during mine operations may provide more precise or improved indicators, enhanced completion criteria or more cost effective or alternative rehabilitation techniques. If rehabilitation goals are anticipated to be changed, the relevant performance indicator and completion criteria may
also require amendment. Proposed or anticipated changes to rehabilitation goals, performance indicators for a domain need to acknowledge the requirements as stated in the EA. Departures from the EA will require liaison with the regulatory authority for comment or approval.

Rehabilitation implementation and performance indicators will be required to be progressively monitored to collate adequate data and information towards the assessment of the risks, either positive or negative, towards archiving the completion criteria. Potential negative risks can be investigated, and corrective or preventative actions developed to ensure environmental harm is minimised.

Overarching performance indicators and completion criteria have been proposed in Table 11-5. The sub-criteria will be developed based on the monitoring of progressive rehabilitation and the completion criteria reviewed every three to five years. The completion criteria will be deemed as having been met when the post mining land use is self-sustaining. That is, where vital ecosystem process and functions are in place supporting a diverse, adaptable, resistant and resilient vegetation and fauna community. Indicators have been chosen based on scientific principles, practical measurement, value of data obtained and their cost effectiveness.

BioCondition assessments in accordance with the BioCondition Assessment Manual (Queensland Herbarium 2015) will be undertaken prior to disturbance to provide an ecosystem baseline. The baseline BioCondition assessment will enable site comparison of ecosystem structure and function including vegetation composition, substrate characteristics, nutrient cycles, animal – plant interactions, ecosystem exchanges and habitat needs. Completion criteria will be regularly reviewed for continual improvement to reflect improved knowledge and work practices in collaboration with key stakeholders.

### 11.11 Post-mining Indicators and Completion Criteria

Since the release of the EIS Central Queensland Coal has committed to not retaining voids. Central Queensland Coal has also committed to destocking the majority of the Mamelon Property and ML to enable natural regeneration of the non-mining areas such as the riparian zones of Deep Creek and Tooloombah Creek. The destocking is to also enable land management activities to be consistent with desired biodiversity management outcomes that will be developed through the Projects offset planning. The following is an updated discussion relating to post-mining indicators and completion criteria.

The attainment of post mining rehabilitation goals through the nomination of strict performance indicators or completion criteria during mine planning or development may not be entirely beneficial. Monitoring and reviewing of the implementation of the rehabilitation strategies as discussed previously during mine operations may provide more precise or improved indicators, enhanced completion criteria or more cost effective or alternative rehabilitation techniques.

Overarching performance indicators and completion criteria have been updated from those in the EIS and are presented in Table 11-5. The sub-criteria will be developed based on the monitoring of progressive rehabilitation and the completion criteria reviewed every three to five years. The completion criteria will be deemed as having been met when the post mining land use is self-sustaining. That is, where vital ecosystem process and functions are in place supporting a diverse, adaptable, resistant and resilient vegetation and fauna community. Indicators have been chosen based on scientific principles, practical measurement, value of data obtained and their cost effectiveness.
If rehabilitation goals are anticipated to be changed, the relevant performance indicator and completion criteria may also require amendment. Proposed or anticipated changes to rehabilitation goals, performance indicators for a domain need to acknowledge the requirements as stated in the EA. Departures from the EA will require liaison with the regulatory authority for comment or approval.

Rehabilitation implementation and performance indicators will be required to be progressively monitored to collate adequate data and information towards the assessment of the risks, either positive or negative, towards archiving the completion criteria. Potential negative risks can be investigated and corrective or preventative actions developed to ensure environmental harm is minimised.

11.12 Rehabilitation Monitoring and Measurement

Monitoring will be carried out to ensure Central Queensland Coal obtains a representative dataset to enable progressive certification of rehabilitation under Chapter 5A of the EP Act. The responsibility for all environmental monitoring and management will be undertaken by Central Queensland Coal’s Environment Manager. Attainment of the site’s rehabilitation performance and completion criteria will be the responsibility of Central Queensland Coal.

The scope of environmental work will be based on the Project’s Environmental Management System (EMS) and the plans and procedures that the EMS provides for, including rehabilitation measures. Key management plans which will provide for comparative reference monitoring sites (against which the results of the Project will be compared), monitoring methods and reporting that relate to rehabilitation are:

- Rehabilitation Management Plan;
- Erosion and Sediment Control Plan;
- Receiving Environment Monitoring Plan;
- Water Management Plan;
- Land Use Management Plan; and
- Progressive Rehabilitation and Closure Plan.

Rehabilitation monitoring will comprise permanent monitoring locations at which visual and photographic surveys, transects / quadrats, ecosystem function analysis and remote sensing will be applied to determine change. It will specify the location of monitoring sites on disturbed areas and reference sites undisturbed by mining, as well monitoring frequency, tools, personnel and reporting protocols.

Rehabilitation monitoring will also include recording the history of rehabilitation activities in any one area so that the performance of a rehabilitation practice can be related to its results. This would include, for example, ground preparation measures, topsoil source, handling and resprreading rates, seeding source and application, and meteorological information such as rainfall, temperature and wind speed.

The ongoing monitoring of the management measures and assessment of attainment of performance indicators will possibly identify departures from the intended goals. Progressive risk assessments will be undertaken towards the degree of the achievement of the rehabilitation goal and long-term sustainability of the rehabilitation and will consider the probability of causing environmental harm. Corrective or preventative actions can be identified and developed to achieve the stated goals. Alternatively, if a corrective action cannot be defined or developed, alternative goals can be established.

Conversely, where monitoring provides evidence of the attainment of the intended goals or negligible potential for potential environmental harm, the monitoring may become unnecessary. Any reduced monitoring will be required to be negotiated and approved by the regulatory authority prior to implementation.
11.13 Relinquishment

An objective of rehabilitation is to facilitate relinquishment of the mining lease and EA and release Central Queensland Coal from ongoing liability for the land. The relinquishment of the mining lease and surrender of the EA requires the appropriate application forms to be completed and adequate information to be provided within a final rehabilitation report. The rehabilitation report prepared for this will be based on the results of Central Queensland Coal’s rehabilitation monitoring and will include evidence that the rehabilitation meets the completion criteria.

The attainment of completion criteria is an important component of the certification process and will be comprehensively discussed within the rehabilitation report. The rehabilitation report will provide definitive information on the assessment of performance indicators and the overall success of the rehabilitation for the duration of the rehabilitation. The rehabilitation report will include interpretation or discussion by appropriately qualified people, relevant to the scope of the rehabilitation and an overall statement of compliance with the stated performance criteria. Rehabilitation must be to the satisfaction of the administering agencies and at a state where there will be no residual risk before any financial assurance held against the Project will be released.

11.14 Conclusion

Specific rehabilitation and decommissioning measures to avoid or minimise any impacts will be identified in the EA and ultimately the Plan of Operations and the MCP that will be finalised prior to the commencement of mine closure activities. Should guidelines be issued regarding the preparation of a PRCP, this will be completed in place of a Plan of Operations and MCP.

It may be the case that the best beneficial use of some of the supporting infrastructure is to leave the infrastructure in place to support the region. This will be discussed with the relevant authorities and landholders prior to formalising the decommissioning strategy. If the preferred outcome is to leave some of the infrastructure components *in situ* as operating infrastructure, Central Queensland Coal will facilitate the transfer of operating licences and obligations to the relevant parties.

Rehabilitation will occur progressively throughout the life of the Project to create a low maintenance, geotechnically stable landform commensurate with the agreed final land use.

11.15 Commitments

In relation to rehabilitation, Central Queensland Coal’s updated commitments are provided in Table 11-6.

Table 11-6 Commitments – rehabilitation and decommissioning

<thead>
<tr>
<th>Commitment</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A Progressive Rehabilitation and Closure Plan will be prepared once guidance has been formalised by the Queensland Government.</td>
<td></td>
</tr>
<tr>
<td>A RMP will be developed based on objectives and goals that seek to provide predetermined land uses for the different land units of the mine. Note if PRCP guidelines are issued, the PRCP will be prepared in place of a RMP.</td>
<td></td>
</tr>
<tr>
<td>A MCP will be prepared outlining the specific operational activities required to complete the rehabilitation and decommissioning of the Project. Note if PRCP guidelines are issued, the PRCP will be prepared in place of a RMP.</td>
<td></td>
</tr>
<tr>
<td>Implementation of a Project Erosion and Sediment Control Plan, developed by a suitably qualified person in accordance with relevant legislation and guidelines.</td>
<td></td>
</tr>
<tr>
<td>Rehabilitation to be non-polluting and consistent with the environmental values as per the Environmental Protection (Water) Policy 2009.</td>
<td></td>
</tr>
</tbody>
</table>
Commitment

Provide landforms with the same or similar land use capabilities and / or suitability prior to the disturbance, unless other beneficial land uses are pre-determined and agreed with key stakeholders (post-mining land owners, managers and relevant regulators).

Rehabilitate disturbed land so that it presents a negligible safety or environmental risk in terms of stability.

Provide land that is self-sustaining to agriculture or ecosystem processes where maintenance requirements are negligible and consistent with an agreed post-mining land use.

Maintain the water quality, leaving waterways and aquifers with water quality and quantity acceptable for existing and future users within or surrounding the site.

Continuation and / or restoration of biodiversity and ecological integrity of areas affected by mining within the mining lease.

Preservation of downstream water quality for ecological and existing beneficial uses.

The Project Land Use Management Plan will outline weed control measures in accordance with the Biosecurity Act.

Onsite records will be maintained regarding any activities or incidents that have the potential to result in land contamination. An inventory will also be maintained that contains information on storage locations, personnel training and disposal procedures for all chemicals, fuel and other potential contaminant uses on site.

Establishment of a low maintenance, geotechnically stable landform commensurate with natural regeneration, nature conservation and grazing land uses.

Shape the created landforms to the extent practical to appear as a natural extension with the surrounding landforms.

Provide habitat for fauna and corridors for fauna movement within the final landform and waterways.

Monitor rehabilitation success in terms of physical, chemical and biological parameters.
